摘要：采用一个波长为785 nm的半导体激光束来囚禁人的肝癌细胞并激发人的肝癌细胞的拉曼光谱,分析模拟微重力三维培养条件下的人肝癌细胞的DNA、蛋白和脂类的生物学物质的变化和表达情况。结果显示,微重力三维培养条件下和平面培养下的人的肝癌细胞的拉曼光谱在527.1 367.1 438.1 659 cm⁻¹处有明显的差异。

Abstract: In our work, HepG2 was cultured onto biodegradable polyglycolic acid(PGA) polymer scaffolds, which was cultured in a rotating cell culture system (RCCS) to form a three-dimensional (3D) and human liver cancer cells cultured in common plate. We detected the spectra of HepG2 cells under two culture conditions and compared the spectra changes of the different cells under two culture conditions. The results show that Raman spectroscopy can differentiate among HepG2 cells under two culture conditions. 527 cm⁻¹ and 1 357 cm⁻¹ peaks of HepG2 cells under simulated microgravity are higher than that of HepG2 cells in common plate. 1 438 cm⁻¹ and 1 659 cm⁻¹ peaks of HepG2 cells under simulated microgravity are lower than that of HepG2 cells in common plate. It is known that 527 cm⁻¹ represents Fe(II), N—N-Mel, 1 357 cm⁻¹ represents Guanine, porphyrins (haemoglobin), lipids, 1 438 cm⁻¹ represents CH₂ deformation (lipids), cholesterol, and 1 659 cm⁻¹ represents Amide I: proteins. These biomaterials which induce these peak changes are possibly related to 3D culture.

Keywords: liver cancer cells simulated microgravity three dimensional culture Raman spectroscopy
