| Abstract<br>The heterogeneity of the continental crust has a first order control on the<br>dynamics of plate tectonic processes and the compositions of the Earth in<br>both time and space. Heterogeneity can be characterized at a variety of<br>scales and in a multitude of tectonic environments, but it is the links<br>between seemingly disparate tectonic settings and crustal levels that are<br>critical in understanding construction of the continents. The focus of this<br>dissertation work is to apply microtextural, microgeochemical, whole rock<br>geochemical and traditional petrographic techniques to study features in<br>both deep and shallow crustal igneous rocks. The goal of these efforts is<br>to better understand the roles that magmatic processes, mafic-felsic<br>magma interaction, and partial melting have on the evolution of<br>continental crust. Two principal field areas were selected, the Gouldsboro |                   |               |   |              |            |            |

pluton in coastal Maine and the Fehr granite in northern Saskatchewan, Canada, because they each represent end-members of the processes involved with the generation, modification, transport, and emplacement of magmas that build continental crust. Evidence for bimodal magmatism preserved in the Silurian age Gouldsboro pluton has led to a refined model for the construction of shallow crustal magma chambers. Research efforts focused on the Neoarchean Fehr granite and Paleoproterozoic Chipman dike swarm have contributed to the current understanding of the links between high temperature metamorphism (migmitization) and the production of new felsic magmas as well as the rheological and chemical influences of mafic-felsic magma interaction in the deep crust. The results of these combined field and laboratory efforts have demonstrated the important role of mafic-felsic magma interaction on the strength and composition of both deep and shallow continental crust and have contributed to the current understanding of the complex links between deep crustal heterogeneity and bimodal magmatism at shallow crustal levels.
