摘要：

河南省新县姚冲钼矿床产于大别造山带, 属于陆-陆碰撞体制的斑岩型矿床, 其流体成矿过程可以分为早、中、晚三个阶段, 分别以石英+钾长石±黄铁矿±磁铁矿、石英±钾长石±辉钼矿±其他硫化物和石英±碳酸盐±萤石组合为标志。热液石英和萤石中发育纯CO₂包裹体(PC型)、CO₂-H₂O型包裹体(C型)、水溶液包裹体(W型)和含子晶多相包裹体(S型)。早阶段石英中发育纯CO₂包裹体、CO₂-H₂O型包裹体和含子晶多相包裹体, 中阶段的石英则发育CO₂-H₂O型包裹体、水溶液包裹体和含子晶多相包裹体, 在晚阶段的无矿石英脉中发育水溶液包裹体和少量的CO₂-H₂O型包裹体, 石英-碳酸盐-萤石脉石英与萤石中只发育水溶液包裹体。早阶段流体包裹体的均一温度为277~380℃, 集中于300~360℃, 盐度变化于3.0%~10.3% NaCleqv之间。中阶段包裹体均一温度介于185~351℃之间, 集中在260~320℃, 盐度介于2.4%~9.3% NaCleqv; 晚阶段包裹体均一温度为139~245℃, 盐度介于0.7%~6.3% NaCleqv之间。中阶段多相包裹体中常见黄铜矿和其他透明矿物, 表明流体具有还原性、过饱和的特征, 是矿石矿物沉淀的主要阶段。估算早、中阶段流体捕获压力分别集中于47~131MPa和26~118MPa, 所对应的成矿深度分别约为4.7km和2.6~4.2km。上述流体包裹体的研究表明姚冲钼矿床的初始成矿流体具有高温、高盐度、富CO₂的特征, 同时预测了深部找矿潜能。

英文摘要：

The Yaochong porphyry Mo deposit in Xinxian County, Henan Province, China, is located in the Dabie orogenic belt. Mo mineralization formed in continental collision settings. The hydrothermal ore-forming process can be divided into the early, middle and late stages, characterized by mineral assemblages of quartz+potassic feldspar±pyrite±magnetite, quartz±potassic feldspar+molybdenum±other sulfides and quartz±calcite±fluorite, respectively. There are four fluid compositional types determined in hydrothermal quartz and fluorite from early to late: pure CO₂, CO₂-H₂O, aqueous and solid-bearing fluid inclusions (FIs). The early-stage quartz contains three of the four types FIs other than the aqueous type. The middle-stage quartz has CO₂-H₂O, aqueous and solid-bearing FIs, without pure CO₂ FIs. In the late stage, a small amount of CO₂-H₂O FIs can be observed in quartz of barren quartz veins, while in quartz-carbonate-(fluorite) veins, only the aqueous FIs are present. Fluid inclusions in the early-stage quartz are homogenized at temperatures of 277~380℃, clustering at 300~360℃, with salinities mainly ranging from 3.0% to 10.3% NaCleqv. Fluid inclusions in the middle stage quartz yield homogenization temperatures of 185℃ to 351℃, with most between 260℃ and 320℃, and salinities of 2.4% to 9.3% NaCleqv. Fluid inclusions in the late stage are totally homogenized at temperatures of 139~245℃, yielding salinities of 0.7%~6.3% NaCleqv. The estimated pressures decrease from a span of 47~131MPa in the early stage, to a range of 26~118MPa in the middle stage, corresponding to a change in depths from 4.7km to 2.6~4.2km. We conclude that the initial fluids forming the Yaochong deposit is high temperature, high salinity and CO₂-rich, and predict that the deeper exploration is potential for ore prospecting.
