**Abstract.** The role and the importance of soil moisture for meteorological, agricultural and hydrological applications is widely known. Remote sensing offers the unique capability to monitor soil moisture over large areas (catchment scale) with, nowadays, a temporal resolution suitable for hydrological purposes. However, the accuracy of the remotely sensed soil moisture estimates has to be carefully checked. The validation of these estimates with in-situ measurements is not straightforward due to the known problems related to the spatial mismatch and the measurement accuracy. The analysis of the effects deriving from assimilating remotely sensed soil moisture data into hydrological or meteorological models represent a more valuable method to test their reliability. In particular, the assimilation of satellite-derived soil moisture estimates into rainfall models at different scales and over different regions represents an important scientific and operational issue.

In this study, the soil wetness index (SWI) product derived from the Advanced SCATterometer (ASCAT) sensor onboard of the Metop satellite was tested. The SWI was firstly compared with the soil moisture time series pattern derived from a continuous rainfall-runoff model (MISDC) to investigate its relationship with modeled data. Then, by using a simple data assimilation technique, the linearly rescaled SWI that matches the variability of modeled data (denoted as SWI\*) was assimilated into the model and the model performance on flood estimation was analyzed. More than three synthetic experiments considering errors on rainfall, model parameters and initial soil wetness conditions were carried out. These experiments allowed to further investigate the SWI potential when uncertain conditions take place. The most significant flood events, which occurred in the period 2000–2009 on five subcatchments of the Upper Tiber River in central Italy, ranging in extension between 100 and 1000 km<sup>2</sup>, were used as case studies. Results reveal that the SWI derived from the ASCAT sensor can be conveniently adopted to improve runoff prediction in the study area, mainly if the initial soil wetness conditions are unknown.
