(Received: May 17, 1995)

UHT-treated milk reduced 3'-{1-[(phenylamino)-carbonyl]-3,4-tetrahydro-2H-pyridin-2-yl}-4-methoxy-6-nitrobenzenesulfonic acid hydrate (XTT). The reduction of XTT is a colorimetric assay for the Maillard reaction intermediate between milk protein and lactose. The rate of the XTT reduction was optimized using the heated model solution of lactose and UHT-treated milk. When the XTT reduction assay was

UHT-treated milks under optimum conditions, the ability of each m XTT significantly reflected the extent of the heat treatment as well as using the hydroxymethylfurfural (HMF) value. In contrast to the HMF, UHT-treated milk gradually decreased depending upon the storage temperature. These results suggest not only that the present XTT method can estimate the extent of heat treatment but also that the reducibility of UHT-treated under a given condition can serve to estimate the storage temperature is known or *vice versa*. The method is much simpler (simple solution containing menadione with milk sample) and quicker (about 10 min) with satisfactory reproducibility than the conventional methods to estimate the Maillard reaction such as the lactulose or HMF determination.
