

Consistent Model Selection of Discrete Bayesian Networks from Incomplete Data

Nikolay Balov

(Submitted on 23 May 2011 (v1), last revised 20 Feb 2012 (this version, v2))

A maximum likelihood based model selection of discrete Bayesian networks is considered. The model selection is performed through scoring function $S(G)$, which, for a given network G and n -sample D_n , is defined to be the maximum log-likelihood $l(G|D_n)$ minus a penalization term $\lambda_n h(G)$ proportional to network complexity $h(G)$, $S(G|D_n) = l(G|D_n) - \lambda_n h(G)$. The data is allowed to have missing values at random that has prompted, to improve the efficiency of estimation, a replacement of the standard log-likelihood with the sum of sample average node log-likelihoods. The latter avoids the exclusion of most partially missing data records and allows the comparison of models fitted to different samples.

Provided that a discrete Bayesian network is identifiable for a given missing data distribution, we show that if the sequence λ_n converges to zero at a slower rate than $n^{-1/2}$ then the estimation is consistent. Moreover, we establish that BIC model selection ($\lambda_n = 0.5 \log(n)/n$) applied to the node-average log-likelihood is in general not consistent. This is in contrast to the complete data case where BIC is known to be consistent. The conclusions are confirmed by numerical examples.
